Basic Git Workflow » **CHEATSHEET**

People, Data, & Drugs
Center for Pharmaceutical Data Science Education

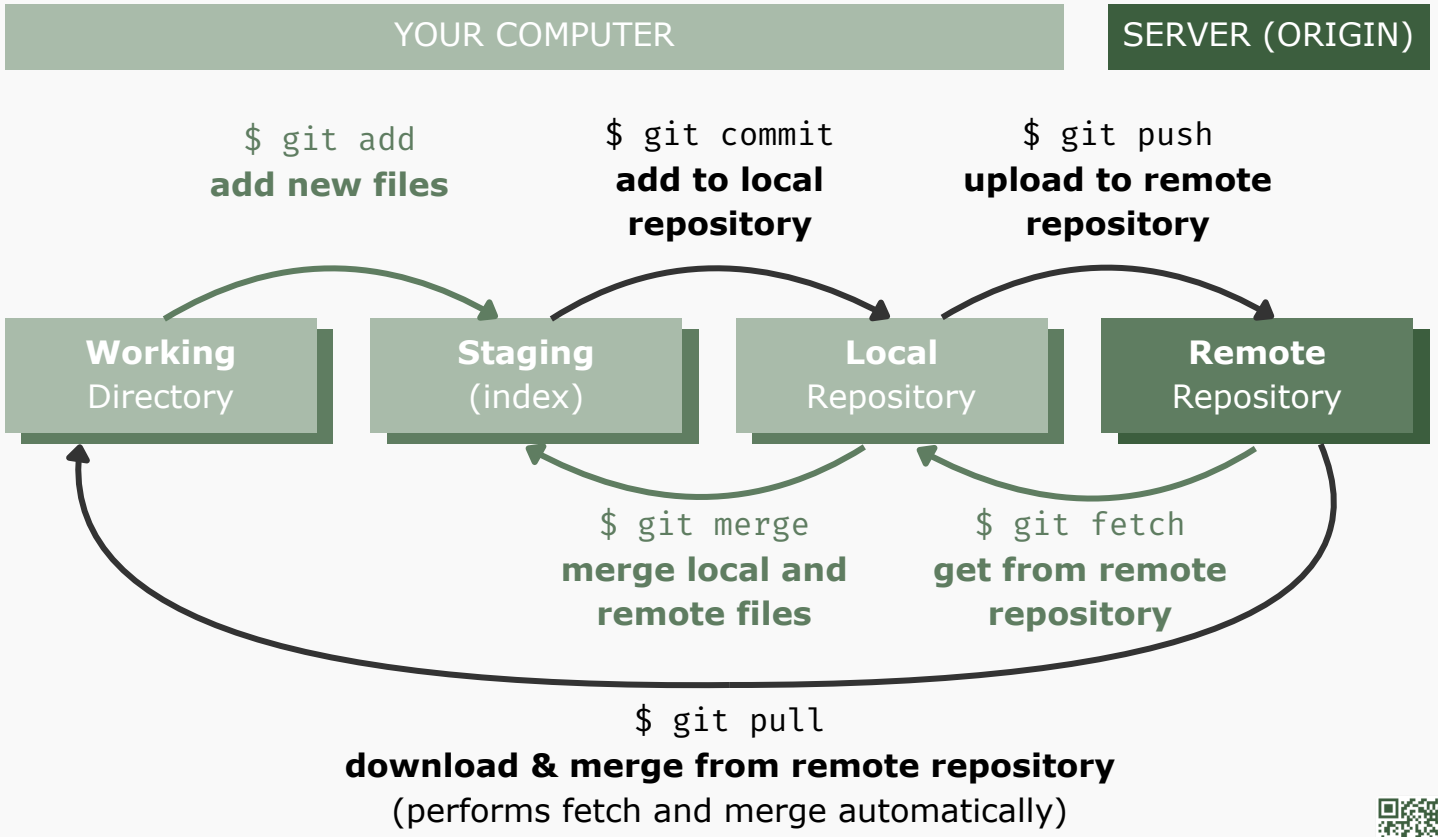
The most important steps when working with Git are:

Commit → Pull → Push

First, commit your changes. Then pull the latest updates to merge them with your work before pushing everything to the remote repository.

What happens locally and remote

Git is like a smart save system for your code. It keeps track of every change you make, so you can always go back to an earlier version if something breaks. It also helps you work with others by syncing your local project on your computer with a remote version (often called *origin*) on the internet. This way, everyone's changes are organized, saved, and combined without accidentally overwriting each other.



Commit message

$ git commit -m "Your commit message"

A commit message briefly explains what changed and why. It documents the project's history and should be clear & concise.
